## ECOREGION Barents Sea and Norwegian Sea <br> STOCK <br> Haddock in Subareas I and II (Northeast Arctic)

## Advice for 2012

ICES advises on the basis of the Joint Russian-Norwegian Fisheries Commission management plan that catches in 2012 should be no more than 318000 t .

## Stock status

Figure 3.4.3.1
Haddock in Subareas I and II (Northeast Arctic). Summary of stock assessment (weights in '000 tonnes). Top right: SSB and F over the years.

The SSB has been above $\mathrm{B}_{\mathrm{pa}}$ since 1989, it has been increasing since 2000 and is presently at the series maximum. Fishing mortality has been around $\mathrm{F}_{\mathrm{MSY}}$ since the mid-1990s. Recruitment at age 3 has been at or above average since 2000. The year classes 2004-2006 are estimated to be very strong. Surveys indicate that the year classes 2008 and 2010 are below average and 2009 year class is around average.

## Management plans

A management plan has been agreed by the Joint Russian-Norwegian Fisheries Commission in 2004 (see Annex 3.4.3). It was modified in 2007 from a three-year rule to a one-year rule on the basis of the HCR evaluation conducted by ICES. The plan is to be used until 2015. ICES has evaluated the modified management plan and concluded that it is in accordance with the precautionary approach but not against the MSY framework.

## Biology

Haddock can vary their diet and eat fish, plankton, or benthos. During the spawning migration of capelin, haddock prey on capelin and their eggs on the spawning grounds. When the capelin abundance is low or when their areas do not overlap, haddock can compensate for the lack of capelin with other fish species such as young herring, or with euphausiids and benthos, which are predominant in the haddock diet throughout the year. Density-dependent growth has been observed for this stock and the present growth rate is low.

## Environmental influence on the stock

Variation in the recruitment of haddock has been associated with the changes in the influx of Atlantic waters to the Barents Sea. Water temperature in the first and second years of the haddock life cycle is one of the factors that determine year-class strength; the probability of good recruitment is very low when the temperature is low. Additionally, a steep rise or fall of the water temperature shows a marked effect on the abundance of year classes. This information on environmental influence is not yet taken into account in the assessment.

## The fisheries

Haddock is mainly fished by trawl as bycatch in the fishery for cod, with some directed fisheries by longline and trawl. TAC regulations are in place. Unreported catches have decreased in recent years and were close to zero in 2009 and 2010. Discarding is illegal in Norway and Russia. Data on discarding are scarce, but attempts to obtain better quantification continue. The fisheries are controlled by inspections at sea and when landing fish, by a requirement to report to catch control points when entering and leaving the EEZs, and by VMS satellite tracking for some fleets.

Catch by fleet Total catch (2010) $=249 \mathrm{kt}$, where $100 \%$ are landings $(74 \%$ trawl, $18 \%$ longline, and $8 \%$ other gear types).

## Quality considerations

The uncertainties in this assessment relate both to catch and survey data. Unreported catches (IUU) and incomplete spatial coverage in surveys have been a problem in recent years, but do not affect the data collected in 2009-2010.

Norwegian sampling is believed to be less precise because of the termination of a Norwegian harbour sampling programme in mid-2009. The poor sampling caused problems in estimating Norwegian catches for the oldest ages.

## Management plan

The current HCR is based on $\mathrm{F}_{\mathrm{pa}}$. However, the $\mathrm{F}_{\mathrm{pa}}$ value has changed in 2011 from 0.35 to 0.47 . ICES advises the continued use of the HCR with target $\mathrm{F}=0.35$ (the newly estimated $\mathrm{F}_{\mathrm{MSY}}$ ). This implies an $\mathrm{F}_{\mathrm{MP}}=0.35$ in 2012, corresponding to landings of 318000 t in 2012. This is expected to keep SSB above $\mathrm{B}_{\mathrm{pa}}$ in 2013 and near the historical maximum.

The management plan was introduced to ensure high and sustainable yield. However, testing and modifications done prior to 2011 were carried out in order to ensure that the HCR was precautionary.

## MSY approach

Long-term stochastic simulations for Northeast Arctic (NEA) haddock show that the $\mathrm{F}=0.35$ currently used in the management plan corresponds to $\mathrm{F}_{\text {MSY }}$ and provides high long-term yield. MSY $\mathrm{B}_{\text {trigger }}$ is chosen as $\mathrm{B}_{\mathrm{pa}}$, which is a biomass that is encountered with low probability if $\mathrm{F}_{\text {MSY }}$ is implemented (ICES, 2011a).

Fishing at $\mathrm{F}_{\text {MSY }}=0.35$ in 2012 corresponds to landings of no more than 318000 t . This is expected to keep SSB above $\mathrm{B}_{\mathrm{pa}}$ in 2013 and near the series maximum.

## PA approach

$\mathrm{F}_{\text {lim }}$ and $\mathrm{F}_{\mathrm{pa}}$ were revised in 2011. The new values of $\mathrm{F}_{\text {lim }}=0.77$ and $\mathrm{F}_{\mathrm{pa}}=0.47$ are higher than the previous values ( 0.49 and 0.35) (ICES, 2011b). The fishing mortality in 2012 should be no more than $\mathrm{F}_{\mathrm{pa}}$, corresponding to landings of less than 399000 t in 2012. This is expected to keep SSB above $\mathrm{B}_{\mathrm{pa}}$ in 2013.

## Additional considerations

Non-reported landings (IUU) for the period 2002-2008 were estimated as ranging from 6 kt to 40 kt (between $4 \%$ and $34 \%$ of the international reported landings). The IUU estimate for 2009-2010 is zero.

The 2011 benchmark assessment on NEA haddock proposed changes in assessment methodology (ICES, 2011c).

## Regulations and their effects

The fishery is regulated by TACs. The fishery is also regulated by a minimum fish size, a minimum mesh size in trawls and Danish seine, a maximum bycatch of undersized fish, maximum bycatch of non-target species, closure of areas with high density of juveniles, and other area and seasonal restrictions. Since January 1997, sorting grids have been mandatory for the trawl fisheries in most of the Barents Sea and Svalbard area.

A real-time closure system has been in force along the Norwegian coast and in the Barents Sea since 1984, aimed at protecting juvenile fish. Based on scientific research vessel data and mapping of areas by hired fishing vessels, fishing is prohibited in areas where the proportion by number of undersized cod, haddock, and saithe combined has been observed by inspectors to exceed $15 \%$ (the size limits vary by species). The time of notice before a closure of an area comes into force is $2-4$ hours for national vessels and 7 days for foreign vessels. Before or parallel to a closure, the Coast Guard requests vessels not to fish in an area where too many small fish have been observed during their inspections. A closed area is not opened until it is documented to be low in juvenile fish by trial fishing within the area by the Surveillance Service.

In addition to the temporary closed areas, some areas are permanently closed either protect juvenile cod and haddock (around Bear Island) or to reduce fishing pressure on coastal cod and to avoid gear conflicts. The use of selective gear technology in the demersal fisheries since 1997 has also reduced the catch and possible discarding of juveniles.

From 1 January 2011 onwards, the minimum mesh size for bottom trawl fisheries for cod and haddock is 130 mm for the entire Barents Sea (before it was 135 mm in the Norwegian EEZ and 125 mm in the Russian EEZ). This change is expected to have a minor impact on the total exploitation pattern for this stock; thus, a recent average exploitation pattern is used in the predictions.

From 1 January 2011, the technical regulations for the demersal fisheries were harmonized so that they now are the same in the Norwegian and Russian EEZs. The present minimum size is 40 cm for haddock (previously it was 44 cm in the Norwegian EEZ and 39 cm in the Russian EEZ). The maximum allowable percentage of fish below the minimum size is $15 \%$ by number of cod, haddock, and saithe combined in the Norwegian EEZ, and $15 \%$ by number of cod and haddock combined in the Russian EEZ. Previously, the maximum percentage was $15 \%$ for each species (cod and haddock) in the Russian EEZ. The effect of these changes is expected to be small as long as the fishing mortality is kept low, as implied by the agreed harvest control rule.

The fisheries are controlled by inspections of the trawler fleet at sea, both by a requirement to report catches at control points when entering and leaving the EEZs, and by inspections of all fishing vessels when landing the fish. Keeping a detailed fishing logbook on-board is mandatory for most vessels, and large parts of the fleet report to the authorities on a daily basis. Discarding is allowed neither in Russia nor in Norway. Discarding is known to be a problem in the longline and trawling fisheries related to the abundance of haddock close to, but below the minimum size.

## Data and methods

Varying natural mortality caused by predation from cod is taken into account in the assessment.

## Information from the fishing industry

Several Norwegian fishing vessels provide regular sampling data for length and age. These data are used to estimate catch-at-age for the corresponding fleets. Russian fishing vessels with observers on-board provide similar information on catch-length distribution and sample fish to receive data on length-age matrices.

## Uncertainties in assessment and forecast

There are no estimates of discarding, but there is known to be a discarding problem in the longline and trawl fisheries. The present Norwegian sampling from commercial catches is believed to have deteriorated in recent years because of the termination of a Norwegian sampling program in mid-2009. Poor sampling caused problems in estimating Norwegian catches for the oldest ages in 2010.

## Comparison with previous assessment and advice

The current assessment estimated the total stock to be about $13 \%$ higher and the SSB $23 \%$ higher in 2010 compared to the previous assessment. F in 2009 is close to that estimated last year.

The basis for the advice is the same as last year.

## Annex 3.4.3 Management plan

The current HCR for haddock is as follows (see details in Protocol of the 36th Session of the Joint Russian-Norwegian Fisheries Commission, 10 October 2007):

- TAC for the next year will be set at level corresponding to Fpa.
- The TAC should not be changed by more than $\pm 25 \%$ compared with the previous year TAC.
- If the spawning stock falls below Bpa, the procedure for establishing TAC should be based on a fishing mortality that is linearly reduced from Fpa at Bpa to $F=0$ at SSB equal to zero. At SSB-levels below Bpa in any of the operational years (current year and a year ahead) there should be no limitations on the year-to-year variations in TAC.

At the $39^{\text {th }}$ Session of the Joint Russian-Norwegian Fisheries Commission in 2010 it was agreed that the current management plan should be used 'for five more years' before it is evaluated.
