## ECOREGION Barents Sea and Norwegian Sea <br> STOCK <br> Saithe in Subareas I and II (Northeast Arctic)

## Advice for 2012

ICES advises on the basis of the management plan implemented by the Norwegian Ministry of Fisheries and Coastal Affairs that catches in 2012 should be no more than 164000 t . Bycatches of coastal cod and $S$. marinus should be kept as low as possible.

## Stock status

Figure 3.4.4.1
Saithe in Subareas I and II (Northeast Arctic). Summary of stock assessment (weights in ' 000 tonnes, recruitment estimates are shown in grey). Top right: SSB and F over the years.

Since 1995, SSB has been well above $\mathrm{B}_{\mathrm{pa}}$ and has decreased in recent years. Fishing mortality has been well below $\mathrm{F}_{\mathrm{pa}}$ since 1996, but has increased after 2005. The 2005 year class is above average, the 2006 year class is estimated to be below average, while the 2007 year class so far seems to be above average strength.

## Management plans

The Norwegian Ministry of Fisheries and Coastal Affairs implemented a harvest control rule (HCR) in autumn 2007 (see Annex 3.4.4). ICES evaluated the Harvest Control Rule in 2007 and concluded that it is consistent with the precautionary approach, providing the assessment uncertainty and error are not greater than those calculated from historical data. This also holds true when for implementation error (difference between TAC and catch).

## Biology

Saithe in Subareas I and II is an important predator on other species in the ecosystem, notably young herring, haddock, and Norway pout. Saithe is a typical migrating fish and makes both feeding and spawning migrations. There are examples of extensive emigration of young saithe from the western part of the Norwegian coast to the North Sea and of older saithe from more northern areas to Iceland and the Faroe Islands. There are few examples of immigration to the Norwegian coast.

## Environmental influence on the stock

There have been variations in distribution and migration patterns over the years, but no link with environmental parameters has been established.

## The fisheries

Norway accounts for more than $90 \%$ of the landings. The gillnet fishery is most intense during winter, purse seine in the summer months, while the trawl fishery takes place more evenly all year around. Coastal cod and S. marinus are caught as bycatch in some of the saithe fisheries (ICES, 2011b,c).

## Catch by fleet Total catch $(2010)=193 \mathrm{kt}$, where 193 kt are landings ( $46 \%$ trawl, 28\% purse-seine, $19 \%$

 gillnet, and $7 \%$ other gear types).
## Quality considerations

The biological sampling from some vessel groups decreased considerably and may have become critically low after the termination of the Norwegian harbour sampling program in mid-2009, e.g. for all gears in the Lofoten area and for purse seine and handline in all areas in 2010. Following the 2010 benchmark the retrospective pattern of the assessment has been less severe.

## Management plan

Following the agreed management plan implies a TAC of 164000 t in 2012. The SSB is expected to decrease by $11 \%$ in 2012 and to remain above $\mathrm{B}_{\mathrm{pa}}$ at the beginning of 2013 .

The objectives of the HCR are to maintain high long-term yield, year-to-year stability, and full utilization of all available information on the stock dynamics. The plan aims to maintain target F at $\mathrm{F}_{\mathrm{pa}}=0.35$ and minimize betweenyear TAC change to $\pm 15 \%$, unless SSB falls below $B_{p a}$ in which case the fishing mortality should be reduced linearly from $F_{p a}$ at $S S B=B_{p a}$ to 0 at $S S B=0$.

Preliminary stochastic simulations show that the highest long-term yield is obtained at F values lower than the $\mathrm{F}=0.35$ currently used in the management plan. More work on this is needed to determine an $\mathrm{F}_{\mathrm{MSY}}$ value that could be considered as a basis for changing the harvest control rule.

## PA approach

The fishing mortality in 2012 should be no more than $\mathrm{F}_{\mathrm{pa}}$, corresponding to landings of less than 178000 t in 2012. This is expected to keep SSB above $\mathrm{B}_{\mathrm{pa}}$ in 2013 .

## Additional considerations

The ICES advice is based on a harvest control rule adopted by the Norwegian authorities. The stock is exploited by fleets from a number of nations which acquire fishing rights by quota swaps with Norway. In addition, Russia sets a small quota for the Russian zone. ICES considers that its advice applies to all catches of Northeast Arctic saithe. Russian catches account for around $5 \%$.

Preliminary long-term stochastic simulations suggest that $\mathrm{F}_{\mathrm{MSY}}$ could be lower than the current $\mathrm{F}_{\mathrm{MP}}$.

## Regulations and their effects

TAC regulations are in place for this stock. Norway and Russia have set national measures applicable to their EEZ. Since 2007 the catch has been less than the TAC. However, in 2010 this difference was less than in previous years.

In the Norwegian fishery, quotas may be transferred between fleets if it becomes clear that the quota allocated to one of the fleets will not be taken. In addition to quotas, the fisheries are managed by minimum mesh size, minimum fish size, bycatch regulations, area closures, and other area and seasonal restrictions. Furthermore, sorting grids are used in the trawl fishery.

Since the early 1960s, purse-seiners and trawlers have dominated the fishery, with a traditional gillnet fishery for spawning saithe as the third major component. The purse-seine fishery is conducted in coastal areas and fjords. Historically, purse-seiners and trawlers have taken, approximately, equal shares of the catches. Regulation changes led to a reduction in the amounts being taken by purse-seiners after 1990.

Discarding is illegal, but may occur when trawlers targeting cod catch saithe without having a quota for saithe. In the purse-seine fishery, slipping has been reported, mainly related to minimum size of fish in the catch. There is no quantitative information on discarding.

On 1 March 1999, the minimum fish size was increased to 45 cm for trawl and conventional gears, and to 42 cm (north of Lofoten) and 40 cm (between $62^{\circ} \mathrm{N}$ and Lofoten) for purse-seine, with an exception for the first 3000 t purse-seine catch between $62^{\circ} \mathrm{N}$ and $66^{\circ} 33^{\prime} \mathrm{N}$, where the minimum fish size remains at 35 cm .

A real-time closure system has been in force along the Norwegian coast and in the Barents Sea since 1984, aimed at protecting juvenile fish. Based on scientific research data and mapping of areas by hired fishing vessels, fishing is prohibited in areas where the proportion by number of undersized cod, haddock, and saithe combined has been observed by inspectors to exceed $15 \%$ (the size limits vary by species). The time of notice before a closure of an area comes into force is $2-4$ hours for national vessels and 7 days for foreign vessels. Before or parallel to a closure, the Coast Guard requests vessels not to fish in an area where too many small fish have been observed during their inspections. A closed area is not opened until a low percentage of juvenile fish is documented by trial fishing within the area by the Surveillance Service.

## Uncertainties in assessment and forecast

Discarding is illegal, but is known to occur in some fisheries. No estimates of discarding are available for assessment
The biological sampling of some vessel groups may have become critically low after the termination of the Norwegian harbour sampling programme in mid-2009.

## Comparison with previous assessment and advice

The current estimates of SSB for 2010 and the F for 2009 are consistent with the previous assessment.
The basis for the advice is the same as last year.

## Annex 3.4.4 Implemented management strategy for saithe in Subareas I and II

The harvest control rule as communicated to ICES by the Norwegian Ministry of Fisheries and Coastal Affairs contains the following elements:

- Estimate the average TAC level for the coming 3 years based on $F_{p a}$. TAC for the next year will be set to this level as a starting value for the 3-year period.
- The year after, the TAC calculation for the next 3 years is repeated based on the updated information about the stock development. However, the TAC should not be changed by more than $+/-15 \%$ compared with the previous year's TAC.
- If the spawning-stock biomass (SSB) in the beginning of the year for which the quota is set (first year of prediction), is below $B_{p a}$, the procedure for establishing TAC should be based on a fishing mortality that is linearly reduced from $F_{p a}$ at $S S B=B_{p a}$ to 0 at $S S B$ equal to zero. At $S S B$ levels below $B_{p a}$ in any of the operational years (current year and 3 years of prediction) there should be no limitations on the year-toyear variations in TAC.
